## EXECUTIVE SUMMARY

Ballara, S.L. (2019). A descriptive analysis of all ling (Genypterus blacodes) fisheries, and CPUE for ling fisheries in LIN 5\&6, from 1990 to 2017. New Zealand Fisheries Assessment Report 2019/49. 88 p.

Updated descriptive analyses for all New Zealand ling fisheries are presented, incorporating data up to the 2016-17 fishing year. The overall 2016-17 ling catch increased to 15000 t , compared to levels of around 13000 t from 2012-13 to 2015-16. However recent catches remain lower than the landings from the 1991-92 to 2007-08 fishing years. The Southland fishery had the largest overall catch of any fishery in 2016-17. The distribution and size of trawl fishery landings showed little change, but catches increased in all areas. Overall trawl landings were higher than those taken in 2015-16, but lower than those taken during the early to mid-2000s. The line fishery catch distribution was quite similar to previous years, although line catches in 2016-17 increased overall, with most of the increase occurring at Bounty, East NI, East SI, and Sub-Antarctic, but with a notable decrease for Chatham. The line fishery catch was markedly lower than in the most productive years (1992-2002), but relatively consistent with the pattern of landings since 2003.

Series of CPUE for commercial line and trawl fisheries targeting ling on the Sub-Antarctic (LIN 5\&6, 1991-2017) were updated. Important variables in the autolongline model included total hooks, statistical area, and vessel, and important trawl variables included location and target species. Since the early 1990s the standardised indices for line fisheries have varied but show an overall decreasing trend. The line spawning CPUE was marginally higher than the CPUE in the non-spawning area. The overall line fishery trends for all indices are similar to previous analyses, and do not match the bottom trawl CPUE trend or trawl survey indices.

## 1. INTRODUCTION

This document reports on Specific Objective 1 of Project LIN201701, which has an overall objective "To carry out a stock assessment of ling (Genypterus blacodes) in the sub-Antarctic (LIN 5/6) including estimating biomass and stock status". It includes a descriptive analysis of the commercial catch and effort data for ling from LIN 2, 3\&4, 5\&6, 6B (Bounty Plateau) and 7, and an update of the standardised catch-per-unit-effort (CPUE) analyses from the ling longline fisheries for LIN 5\&6 (Sub-Antarctic) with the addition of data up to the end of the 2016-17 fishing year. Specific Objective 1 was "To carry out a descriptive analysis of the commercial catch and effort data for ling (LIN 5\&6) in the sub-Antarctic, and update the standardised catch and effort analyses." This objective requires that LIN 5\&6 CPUE be updated only for the series used in the most recent previous stock assessments of the Sub-Antarctic stock.

Earlier descriptive analyses of commercial catch and effort data for ling were completed for the fishing years 1989-90 to 1998-99 (Horn 2001) and 1989-90 to 2004-05 (Horn 2007b). These reports showed how the ling fisheries in the New Zealand EEZ had developed and operated, and defined seasonal and areal patterns of fish distribution. The work presented here updates an analysis by Dunn \& Ballara (2019) which included data up to the fishing year 2015-16 (fishing years run 1 October - 30 September); i.e., catch by area by method, to indicate whether any marked changes had occurred in the fisheries in the last year. Horn (2007b) provided a detailed description of the methods used to extract and summarise Fisheries New Zealand landings data.

An analysis updating series of CPUE indices from target line fisheries for ling on the Sub-Antarctic (LIN 5\&6) is also presented here. CPUE analyses of these fisheries were most recently reported by Ballara \& Horn (2015). These fisheries, along with the Chatham Rise, WCSI, Cook Strait and the Bounty Plateau line fisheries, account for over $95 \%$ of the line-caught ling. The principal lining method in all areas is bottom longline. These CPUE series are used as inputs into stock assessments.

## 2. CATCH DATA

### 2.1 Methods

Catch-effort, daily processed, and landed data were extracted from the Fisheries New Zealand catcheffort database "warehou" as extract 11384 and consist of all fishing and landing events associated with a set of fishing trips that reported a positive catch or landing of hoki, hake, or ling from fishing years 1989-90 to 2016-17. This included all fishing recorded on Trawl Catch, Effort and Processing Returns (TCEPRs); Trawl Catch Effort returns (TCERs); Catch, Effort and Landing Returns (CELRs); Lining Catch Effort Returns (LCERs); Lining Trip Catch Effort Return (LTCERs); Netting Catch Effort Landing Returns (NCELRs); and included high seas versions of these forms. Catch and effort data for ling from the Fisheries New Zealand Observer Sampling Programme (hosted by NIWA in the cod database) were also extracted.

Data were checked for errors, using simple checking and imputation algorithms similar to those used by Ballara \& O'Driscoll (2017). Data were also groomed for errors using simple checking and imputation algorithms developed in the statistical software package ' R ' ( R Core Team 2017). Individual tows were investigated and errors were corrected using median imputation for start/finish latitude or longitude, fishing method, target species, tow speed, net depth, bottom depth, wingspread, duration, and headline height for each fishing day for a vessel. Range checks were defined for the remaining attributes to identify outliers in the data. The outliers were checked and corrected if possible with mean imputation on larger ranges of data such as year to vessel, target species and fishing method for a year or month, or the record was removed from the data set. Statistical areas were calculated from positions where these were available. Transposition of some data was carried out (e.g., bottom depth and depth of net).

The fishing methods examined were deepwater bottom trawl, deepwater midwater trawl, inshore bottom trawl, inshore midwater trawl, line, setnet, and fish pots. The distinction between deepwater and inshore trawls was not based on depth or position, but rather on the form type that the catch was reported on. TCEPR records were classified as deepwater; CELR and TCER records were classified as inshore.

New Zealand ling are managed as eight administrative Quota Management Areas (QMAs), although five of these (LIN 3, 4, 5, 6, and 7) (Figure A1) currently produce about 95\% of the New Zealand landings of ling. Research has supported the assumption of at least five major biological stocks of ling in New Zealand waters (Horn 2005): Chatham Rise (LIN 3 and LIN 4), Sub-Antarctic incorporating Campbell Plateau and Stewart-Snares shelf (LIN 5, and LIN 6 west of $176^{\circ}$ E), Bounty Plateau (LIN 6 east of $176^{\circ}$ E), west coast South Island (LIN 7 west of Cape Farewell), and Cook Strait (those parts of LIN 2 and LIN 7 between latitudes $41^{\circ}$ and $42^{\circ} \mathrm{S}$ and longitudes $174^{\circ}$ and $175.4^{\circ} \mathrm{E}$, equating approximately to Statistical Areas 016 and 017). These stocks are referred to as LIN 3\&4, LIN 5\&6, LIN 6B, LIN 7WC, and LIN 7CK, respectively.

The catch data from the statistical areas were combined so that the groupings generally approximated the various administrative ling stocks, with two major exceptions. The Bounty Plateau section of LIN 6 was examined separately as it is believed to contain a distinct biological stock (Horn 2005), and a Cook Strait area comprising parts of LIN 2 and LIN 7 was created. The fishery areas are labelled in this section as North North Island (North NI), East North Island (East NI), East South Island (East SI), Chatham, Southland, Sub-Antarctic, Bounty, West South Island (West SI), and Cook Strait (Table A1, Figure A2). Data for the Chatham Rise and Sub-Antarctic were grouped by statistical area as follows: Chatham Rise (LIN 3\&4): 018-024, 049-052, 301, 401-412, and Sub-Antarctic (LIN 5\&6): 025-031, 302, 303, 501-504, 601-606, 610-612, 616-620, 623-625. Consequently, the grouping of some statistical areas may appear erroneous, but has been done in a way that best approximates biological stocks. For example, Statistical Areas 302, 303, and most of 026 are in LIN 3, but they have been included in the Sub-Antarctic analysis, as ling in these areas probably derive from the Sub-Antarctic stock because the Stewart-Snares shelf and Campbell Plateau are the closest submarine shelves to these statistical areas.

### 2.2 Catch data results

Annual estimated catches, reported landings, and TACCs by area, from all methods combined, are listed in Table A2, and shown in Figure A3. In 2016-17, landings from Fishstocks LIN 3, LIN 4 and LIN 6 were significantly under-caught relative to their TACCs, and the LIN 1, 2 , 5 and 7 TACCs were slightly over-caught. The estimated catch totals for each year ranged between 85 and $101 \%$ of the Monthly Harvest Return (MHR) landings. Substantial catches were taken in all areas, but most catches were taken in five areas around the South Island: East SI, Chatham, Southland, Sub-Antarctic, and West SI. This pattern of catches was consistent with ling distributions derived from research trawls (Anderson et al. 1998). There were some changes to the proportions of catch contributed by some areas before and after 2000. Catches from the Sub-Antarctic increased in the latter period (although have been lower from 2008-09 to 2015-16), while those from Chatham declined. By catch weight, the largest overall fishery in 2016-17 was the Southland fishery. Most ling catches since 1989-90 were reported on TCEPR or CELR forms, and were caught by bottom trawling or bottom longlining, mainly when the target species was hoki or hake (Table A3, Figure A3).

Overall, trawl-caught ling were taken mainly by bottom trawlers targeting ling or hoki, although the proportion of ling caught in hoki target tows has decreased since the mid 2000s (Figure A4). Ling are caught all year around, but more commonly between June and January (Figure A4). They are generally caught by mid-sized vessels. Compared to the previous fishing year, the 2016-17 trawl fishery catches in all areas increased (Table A4, Figure A4).

The deepwater bottom trawl fishery was still important in the Southland and Sub-Antarctic areas with annual catches generally greater than 2000 t (Table A4). Catches from the Sub-Antarctic increased from
the late 1990s to peak at more than 4900 t in 2003-04. Only $750-1500 \mathrm{t}$ was reported from 2009-10 to 2011-12, but there was a large increase to 3390 t taken in 2012-13, with a decrease to just over 1500 t in 2015-16, and a subsequent increase to 1900 t in 2016-17. Southland catches ranged from 1900 to 3300 t , with 3200 t taken in 2016-17. West SI catches have been greater than 500 t since 1996-97, and in 2016-17 increased slightly to 980 t. Chatham and East SI catches increased slightly in 2016-17. Total landings from the deepwater midwater trawl fishery have been relatively low since 2006-07, ranging between 125 and $630 t$, and decreased slightly to $590 t$ in 2016-17 (Table A4).

For the inshore bottom trawl fishery, there were low levels of catches (i.e., generally less than 100 t annually) in all areas except for Sub-Antarctic, and Bounty, where catches were negligible or zero (Table A4). There were increased catches in Southland and West SI by inshore trawl from about 200809. Catches from the inshore midwater trawl fishery were negligible in all areas except West SI and Cook Strait; catches in 2016-17 in both of those areas were low (Table A4).

The catch from the ling longline fishery is taken mainly by bottom longliners targeting ling; landings occur all year around, but more commonly between June and December (Figure A5). Smaller vessels dominate this fishery. Relative to 2015-16, the line catches in 2016-17 increased overall, with most of the increase taking place in the Bounty, East NI, East SI, and Sub-Antarctic areas, although with a notable decrease for the Chatham area (Table A4, Figure A5). The line fishery catches by area varied markedly between years (Table A4). The Chatham area was still the most productive, but recent catches were only about a third of those taken at its peak in the mid-1990s.

The setnet fishery catches have been negligible in all areas except East SI (Table A4). The 2016-17 catches in East SI remained low.

Catches from fish pots were generally recorded only from East SI, where annual landings were generally between 10 and 50 t , until 2015-16 but have since been over 100 t (Table A4). Interestingly, the last two years have also seen increases in catches by this method in North NI, East NI, West SI, and Cook Strait.

Total catches from the EEZ increased to 15000 t , compared to levels of around 13000 t from 2012-13 to 2015-16. Catches from 2008-09 to 2015-16 were all below those from the historically high catch period of 1991-92 to 2007-08 (Table A4).

### 2.1.1 East SI and Chatham (LIN 3\&4) catch data

On the Chatham Rise (LIN 3\&4), ling trawl catch was taken mainly by bottom trawlers targeting hoki (Table B1, Figure B1). The proportion of ling caught in hake target tows has decreased since 2009 (Figure B1). In general, most catch was taken between September and June, often with a peak from September to November (Table B2, Figure B1). Most of the trawl catch was spread out across ECSI (Statistical Areas 021-023) and the Chatham Rise (Statistical Areas 401-404, and 407-410) (Figures B1-B3). More than $98 \%$ of the Chatham Rise trawl catch is reported on the TCEPR form, and $95 \%$ taken by bottom trawling (Figure B1). The trawl catch since 2010 has been lower than 1200 t ; 752 t in 2014 was the lowest of all years since 1990, and in 2016-17 at 1171 t the catch was still relatively low (Table B2). Mean duration, distance, speed, and depth per tow have remained relatively unchanged (Figure B4), although mean hoki catch per tow has increased since 2004. Overall catches and number of tows by year were higher for larger vessels, although overall tow duration by year was sometimes higher for smaller inshore vessels in recent years (Table B3).

Chatham Rise (LIN 3\&4) line fisheries caught ling throughout the year, but most catch is taken from July to November (Table B2; Figure B5). Most of the line catch is taken in Statistical Areas 020-021, 049, 052, 401-404, and 410 (Figures B5, B6, and B7). Over 99\% of the catch was taken by the bottom longline method, and $99 \%$ of the catch was from lines targeting ling (Figure B5), and by larger vessels using fewer than 5000 hooks/day (Table B3, Figure B8).

### 2.1.3 Southland and Sub-Antarctic (LIN 5\&6) catch data

In Southland and the Sub-Antarctic (LIN 5\&6), ling trawl catch was taken mainly by bottom trawlers targeting hoki or ling (Table C1, Figure C1). In general, catch was taken all year around, although higher catches were taken between September and December (Table C2, Figure C1). Most of the trawl catch was caught in Statistical Areas 027, 028, 030, 602 and 603 (Figures C1-C3). In general, trawlcaught ling were taken mainly along the edge of the Stewart-Snares shelf, in the Norwegian Hole, at Puysegur Bank, and, in smaller amounts, on the northern Campbell Plateau, and southern Auckland Islands shelf. More than $98 \%$ of the trawl ling catch in the Sub-Antarctic is reported on the TCEPR form, $96 \%$ taken by bottom trawling, and 50\% of catch by target ling trawling (Figure C1). For vessels targeting hoki, hake or ling, bottom tows showed a decrease in mean distance, speed, and depth of net and bottom since 2002 (Figure C4), which can be attributed in part to the increased bottom trawl catches by smaller Korean vessels. Mean duration increased marginally. Overall catches, number of tows, and duration by year were higher for vessels larger than 28 m (Table C3).

Sub-Antarctic (LIN 5\&6) line fisheries caught ling throughout the year, although very little catch is taken in July-August and December-January (Table C2, Figure C5). Most of the line catch is taken in Statistical Areas 030, 602-605, 610-611, 618, and 619 (Figures C5, C6, and C7). Most Puysegur (Statistical Area 030) catch was taken from October to December, and most non-Puysegur catch from December to July (Figure C5b). Over 99\% of the catch was taken by the bottom longline method targeting ling (Figure C5), and by vessels greater than 28 m using fewer than 5000 hooks per day (Table C3, Figure C8).

### 2.1.4 West SI (LIN 7 WC) catch data

The LIN 7 WC trawl catch was mainly bycatch in the much larger hoki target fishery, although the ling caught in hake or ling target tows increased from 2005 (Table D1, Figure D1). In general, most catch was taken between May and October, often with a peak from June to September (Table D2, Figure D1). Most of the trawl catch was taken in Statistical Areas 033-036, in the North shallow and Deep subareas (Figures D1-D3).

About $84 \%$ of the trawl catch was recorded on TCEPR forms, and $58 \%$ of the catch taken by bottom trawling, although with only 5\% of ling trawl catch targeted (Figure D1). Mean duration, distance, speed, and depth per tow decreased after about 2003-04 (Figure D4), which can be attributed in part to the increased bottom trawl catches since 2002 by smaller Korean vessels targeting hake, and changes in midwater and bottom trawl vessels. Overall catches by year were higher for larger vessels, although overall number of tows and tow duration by year were higher for smaller inshore vessels less than 28 m in length (Table D3).

LIN 7 WC line fisheries caught ling throughout the year, but most catch was taken from July to November (Table D2, Figure D5). Over 98\% of the catch was taken by the bottom longline method, with $96 \%$ of the line catch targeted (Figure D5). Most of the line catch was taken in Statistical Areas 032-034 (Figures D5, D6, and D7), and by smaller inshore vessels less than 28 m using fewer than 5000 hooks per day (Table D3, Figure D8).

### 2.1.4 Descriptive analysis summary

The overall 2016-17 ling catch increased to 15000 t , compared to levels of around 13000 t from 201213 to 2015-16. However recent catches remained lower than landings from the 1991-92 to 2007-08 fishing years. The Southland fishery had the largest overall catches of any fishery in 2016-17. The distribution of trawl fishery landings showed little change, but catches increased in all areas. Overall trawl landings were higher than those taken in 2015-16, but lower than those taken during the early to mid-2000s.

The line fishery catch distribution was also quite similar to previous years, although line catches in 2016-17 increased overall, with most of the increase taking place in the Bounty, East NI, East SI, and Sub-Antarctic areas, but with a notable decrease for Chatham. The line fishery catch was markedly lower than in the most productive years (1992-2002), but relatively consistent with the pattern of landings since 2003.

## 3. CPUE ANALYSIS

### 3.1 Methods

## CPUE variables

Variables used in the CPUE analysis are described in Tables E1 and F1 and are generally similar to those used in previous analyses (e.g., Dunn \& Ballara 2019). CPUE indices were calculated using catch per tow (in kilograms) for TCEPR tow-by-tow data, with tow duration offered as an explanatory variable. Longline CPUE was defined as catch per day per statistical area (i.e., daily estimated catch in kilograms by a vessel in a particular statistical area), and number of hooks set per day was offered as an explanatory variable. Catch per day (rather than catch per hook) was used as the unit of CPUE because it has been shown (Horn 2002) that the relationship between catch per hook and the number of hooks set per day is non-linear.

In previous analyses, data were analysed by calendar year rather than fishing year, because of a seasonal trend of higher catch rates in most ling fisheries running across the fishing year (1 October to 30 September) boundary, from about June to December (see Horn 2007a). This created a problem for stock assessment models, where the year definition for CPUE was different. The catch history used in the LIN 5\&6 model is calculated using a September to August year, so that the September trawl catch is included with the similarly high catches immediately after it in October to December, rather than 'on its own' at the end of an October to September year (Masi 2019). Also, the trawl catch-at-age samples are taken from a 5-month period of September to January. Therefore for the current analysis CPUE year was aligned with the model year and shifted to be analysed using a September to August year. The Puysegur line fishery is almost exclusively October to December, and the non-Puysegur line fishery is mainly December to July (see Figure C5b). The trawl fishery occurs all year around, although most heavily in September to December, and least in March to May (see Figure C1). Observer data on female gonad stage clearly show that spawning in both the Puysegur, and Southland and Sub-Antarctic areas is at a peak around September to November (Table F2, Figure F1). Therefore the definitions 'spawning' and 'non-spawning' fisheries were changed to September to December, and January to August respectively. The previous analysis (Ballara \& Horn 2015) used the 'spawning' fishery as Puysegur only September to December, and the 'non-spawning’ fishery as Southland and Sub-Antarctic January to December and Puysegur January to August.

Hence, year was a categorical variable and was defined as a September to August year. Season variables of both month and day of year, and statistical area (statarea) variables were offered to the model.

Vessel was incorporated into the CPUE standardisation to allow for possible differences in fishing ability between vessels. Records with no vessel identification data were excluded from analyses. Data from vessels that fished infrequently were excluded by including data only from "core" vessels, which were those that together reported at least $80 \%$ of ling estimated catches, and were all involved in the fishery for two or more years, and for a substantial number of tows or vessel-days in a year (criteria varied by gear, see below). Vessels not involved in the fishery for at least two years were excluded as they provided little information for standardisations, which could result in model over-fitting (Francis 2001). Individual vessel details were checked for consistency each year.

For line data, total hooks per day and number of sets per day were offered as an untransformed number and as log-transformed data. For trawl data, gear width was not used as an explanatory variable as this
field in the TCEPR form variously contained wingspread and doorspread measurements, and hence, headline height was the only trawl gear dimension variable offered to the model. Grid number, defined as the $0.5^{\circ}$ latitude/longitude square where the catch was taken (V. McGregor, NIWA, pers. comm.) was included all trawl models.

## CPUE data selection

For line fisheries, some vessels recorded individual set data on CELR forms, but most vessels reported a single CELR record for a day's fishing. If uncorrected, this would bias CPUE analyses, as those vessels recording individual events would contribute about four times as many records per day. Consequently, all line data for CELR, LTCER and LCER forms were condensed (catches, hooks, and sets summed for each vessel, day, and statistical area) to ensure that each record represented total catch and effort per statistical area per day. The estimated catch of the top five species per day can be reported on the CELR form, whereas the estimated catch of the top eight species per set can be reported on the LCER and LTCER forms. If there was more than one set recorded in a day, the estimated catch of numerous (up to 20-30) species may be reported for a single day of fishing on LCER and LTCER forms, compared to five species on CELR forms. This can result in small catches being reported in LCER and LTCER records that would not have appeared had CELR forms been used. Therefore the daily aggregate estimated catch of ling was only included with the LCER or LTCER daily aggregate effort record if the catch of that species was ranked amongst the five largest species catches (by weight) for the vessel fishing day and statistical area. As a result of this correction, there were 25 vessel-daystatistical area aggregate records removed from the dataset.

It was identified by the MPI Deepwater Fisheries Assessment Working Group meeting on 8 February 2018 that handbait vessels are more likely to have higher catchrates than autoliners (owing to more hooks being comprehensively and successfully baited than by the auto-baiting process), hence identifying and excluding these vessels from a CPUE analysis is important. It was not simple to use number of hooks per day as a cutoff to define autolongliners, so information was obtained from industry and MPI to identify longline vessel types as either autolongline or handbait. Some vessels were able to be identified as exclusively autolongline or handbait vessels, but there was a set of vessels that were current autolongliners but had potentially previously converted from handbait to autolongline. Hence there were three types of autolongliners identified: "always autolongline" (vessel has always been an autolongliner); "autolongline now" (currently an autolongline vessel, but no information as to whether it converted from handbait to autolongline in the past); and "handbait" (handbait longliner). Overall the "always autolongline" vessels accounted for $89.5 \%$ of the catch, $82 \%$ of vessel-days, but only $24 \%$ of longline vessels, while the "handbait" category made up $56 \%$ of longline vessels (Table E2).

To ensure that the data were in plausible ranges and related to vessels that had consistently targeted and caught significant landings of ling, data were accepted if all the constraints were met (Tables E3 and F3). Core vessel analyses were run for trawl fisheries using TCEPR tow-by-tow data, and for line fisheries using vessel-day data.

For line fishery analyses, data were accepted from the CELR and LTCER forms for target ling and line method BLL (bottom longline) for calendar years 1991-2017 for vessels that had always been an autolongline vessel, and for statistical areas with at least 50 vessel-day-statistical area combined sets (Table E3). Records were excluded if catches were outside of the range $1-35000 \mathrm{~kg}$, and the total number of hooks was outside of the range 50-50 000. Examination of records reporting zero catch indicated that most represented either duplicate records (two records for a particular day, one with and one without catches) or obvious mistakes (two or three days fishing with no catch). Because of the relatively high number of hooks fished in any set, a zero catch of ling in any set that was targeting ling was likely to result either from a reporting error or, if real, some gear malfunction or unsuccessful exploratory fishing. As a result, zero catch records were removed from the data set. There were 73 records having zero ling catch, making up $0.9 \%$ of the records.

Data for bottom trawling were accepted for the September to August years 1991-2017, for target fisheries hoki, hake and ling, and statistical areas with at least 100 tows (Table F3). Records were
excluded if catch weight was greater than 50 t (assumed to be an error), bottom depths were not within $150-1000 \mathrm{~m}$ (known depth range of ling), and duration of trawling was not within $0.2-15$ hours (assumed to be an error).

The data were also analysed as two fisheries within the Southland and Sub-Antarctic stock using all the data records that were accepted into the 'whole stock' analysis. The two fisheries were: "spawning" as September to December, and non-spawning as January to August.

## The CPUE model

Annual unstandardised (raw) CPUE indices were calculated as the mean of the individual daily catch (kg) for a longline or as catch per tow (kg) for TCEPR tow-by-tow data. All series used the lognormal distribution for the positive catch model. For the trawl series, a binomial model based on the presence/absence of ling in each data set was also calculated, with the two models combined using the delta-lognormal method to provide the final series (Vignaux 1994). Estimates of relative year effects were obtained from a stepwise multiple regression method, where the data were fitted using a lognormal model using log transformed non-zero catch-effort data. The predictor variable year was forced into the model (as it is mandatory for a biomass index), and other variables tested for inclusion. A forward stepwise multiple-regression fitting algorithm (Chambers \& Hastie 1991) implemented in the R statistical programming language (R Core Team 2017) was used to select additional predictor variables, and they were entered into the model in the order which gave the maximum decrease in the AIC. The algorithm generates a final regression model iteratively and used the year term as the initial or base model in all cases. The reduction in residual deviance (denoted $r^{2}$ ) was calculated for each single term added to the base model. The term that resulted in the greatest reduction in the residual deviance was then added to the base model, where the change was at least $1 \%$. The algorithm was then repeated, updating the base model, until no more terms were added. A stopping rule of $1 \%$ change in residual deviance was used because this results in a relatively parsimonious model with moderate explanatory power. Alternative stopping rules or error structures were not investigated.

Predictor variables were either categorical or continuous. The variable year was treated as a categorical value so that the regression coefficients of each year could vary independently within the model. The relative year effects calculated from the regression coefficients represent the change in CPUE through time, all other effects having been taken into account, and represents a possible index of abundance. Year was standardised to the first year of the data series and were presented in canonical form (Francis 1999). Variables were either categorical or continuous. Potential continuous variables were modelled as third-order polynomials, although a fourth-order polynomial was also offered for duration (see Tables E1 and F1). Vessel was incorporated into the CPUE standardisation to allow for differences in fishing ability between vessels. Grid number was also incorporated to allow for differences in fishing area in trawl models (Table F1). Model runs with grid number included all cells, top cell (cell with the highest overall catch), the top 5 cells (cells with the highest catches), and complement of the top cells (all cells not in top cells model run) (Figure F2). The index CVs represent the ratio of the standard error to the index. The $95 \%$ confidence intervals were also calculated for each index. Date was included in the catch runs as year and month, or day of year. Interaction terms were not used in the line fisheries, because in the past their inclusion resulted in some implausible vessel coefficients (Dunn et al. 2013), although a year:fishery interaction was used in the Sub-Antarctic model (see below) .

Model fits to the lognormal component of the combined model were investigated using standard residual diagnostics. For each model, a plot of residuals against fitted values and a plot of residuals against quantiles of the standard normal distribution were produced to check for departures from the regression assumptions of homoscedasticity and normality of errors in log-space (i.e., log-normal errors). For the binomial component, model fits were investigated visually using randomised quantile residuals (Dunn \& Smyth 1996). Randomised quantile residuals are based on the idea of inverting the estimated distribution function for each observation to obtain exactly standard normal residuals. For discrete distributions, such as the binomial, some randomisation was introduced to produce continuous normal residuals.

Unstandardised CPUE was also derived for each year from the available datasets. The annual indices were calculated as the mean of the individual daily catch (kg) for line data, or catch per tow (kg) for tow-by-tow data.

The model predictors for each selected variable were plotted, with all other model predictors fixed. These fixed values were chosen to be 'typical' values (see Francis (2001) for further discussion of this method). If different fixed values were chosen, the absolute values on the plotted $y$-axis would change but the trend would be unchanged.

The influence of each variable accepted into the lognormal models was described by coefficient-distribution-influence (CDI) plots (Bentley et al. 2012). These plots show the combined effect of (a) the expected $\log$ catch for each level of the variable (model coefficients) and (b) the distribution of the levels of the variable in each year, and therefore describe the influence that the variable has on the unstandardised CPUE and that is accounted for by the standardisation.

CPUE analyses were undertaken for "core" vessels that were determined for each area analysis using area-specific criteria based on approximately $80 \%$ of ling catch, the number of years of vessel participation, and the number of tows (trawl) or vessel-days (line) per vessel-year (Tables E3 and F3). As there were only ten "always autolongline" vessels, nine of these vessels which had fished in at least two years were chosen, making up $89 \%$ of the Sub-Antarctic longline catch.

The primary Southland and Sub-Antarctic line fishery analysis used data from 1992-2017, and the trawl fishery analysis used data from 1991-2017. Core vessel analyses were run both as a single fishery and as separate spawning and non-spawning fisheries, although there were no data for 2008 and 2013 for the non-spawning line fishery. For the CPUE series estimated for separate fisheries within the Southland and Sub-Antarctic stock, a year:fishery interaction effect was forced into the model. This produced a CPUE series for each of the two fisheries within the stock, but with all other expected variable effects being the same over the fisheries. The autolongline fishery indices were compared to the previous results (all longline vessels using calendar year) from Ballara \& Horn (2015), and single fishery and two fishery results were compared for the spawning and non-spawning data. Autolongline and trawl CPUE indices were also compared with each other, and to Southland and Sub-Antarctic Tangaroa trawl survey biomass indices.

### 3.2 CPUE results

CPUE series for line and trawl-caught ling for Southland and the Sub-Antarctic (LIN 5\&6) are presented here, with tables and figures in Appendix E (line results) and Appendix F (tow-by-tow results).

### 3.2.1 Longline fishery

Sub-Antarctic line fisheries catch ling throughout the year by bottom longline and ling targeting, so only data from this method and target were included in the analysis (Table E3, see Figure C5). Statistical areas that had few days fished (i.e., less than 50 ) throughout the 26 years (overall $1.6 \%$ of vessel-days) were probably attributable to reporting errors or exploratory fishing, so were removed from the final analysis. Further Southland and Sub-Antarctic data constraints included vessels that had always been autolongliners (see section 2.2), catches of 1-35 000 kg , and number of hooks at $50-50000$ per vesselday.

Core vessels for the bottom longline index were defined as those participating in the fishery for at least two years (Figure E1). The core analysis included 6307 records of days fished throughout the 26 years analysed (2430 from the spawning fishery, and 3877 from the non-spawning fishery).The spawning fishery had 14-193 days fished in each year; the non-spawning fishery had 7-451 days per year. Spawning data were more abundant through the first part of the series, with the non-spawning data more abundant in later years. From 1993 to 2002 when the auto-longline fishery was at its peak, line fishing accounted for about $17-37 \%$ of the LIN $5 \& 6$ landings (excluding the Bounty Plateau) (see Tables A4
and C2). The percentage of line catch was lower from 2003 to 2009 ( $8-14 \%$ of the landings), but was again relatively high ( $21 \%$ ) in 2012, and has fluctuated between $5 \%$ and $17 \%$ since then (Tables A4 and C2). The estimated catch from this CPUE data set was $89.5 \%$ of the total estimated catch by line fishing in this area (Table E3). The core analysis included data from nine vessels; six of these had fished in six or more years of the series, and one had fished in 19 years (Figure E1).

For line single fishery CPUE, four variables were selected for the lognormal model, resulting in a total $r^{2}$ of $61 \%$, with $\log ($ total hooks) explaining $54 \%$ of the residual deviance (Table E4). The variables selected into the two-fishery model were similar to the single fishery model, although vessel did not enter that model. In the two-fishery model, log(total hooks) explained most of the variance (60\%), and with vessel included, $62 \%$ of total variance was explained.

The standardised year effects for the single and two fisheries models show variable series with a slightly declining trend (Table E5, Figure E2). The trends in the standardised indices do not closely follow the trends in the unstandardised indices. The variable of number of hooks has the largest impact on the standarised indices (Figure E3). There were similar trends between the three series although the indices in the spawning fishery were generally higher than those in the single fishery, and the non-spawning fishery was generally the lowest (Figure E4). In the spawning series, the high 2010 index and the low 2011 index are based on low numbers of days fishing. There were very wide confidence bounds in 2010 but small confidence bounds in 2011. The trends in the indices changed somewhat from previous analyses (Figure E4b), however this is to be expected due to the changed year definition, vessel definition, vessel selection, and spawning definition, with the apparent 1-year lag seen in the spawning fishery due to the changed year definition. The trends in the CPUE indices also had a poor match to the trend shown by the trawl survey biomass indices (Figure E4c).

Influence plots (Figure E5) showed that total hooks per day had a positive influence from 1998 (except for 2004) when there was less effort with lower total hook numbers; higher catch rates are expected with higher total hook numbers. The vessel influence on CPUE was negative in most years from 1999, although was positive in 2005-2006, and in 2015. For vessel, changes are related to the movement of vessels out of the fishery, and to differing levels of effort by individual vessels. Most vessels had similar expected catch rates, which is not surprising since they are all autolongliners. For statistical area the highest expected catch rates occurred in Statistical Area 030, but rates varied by a factor of less than 2 over all areas. There was a large positive influence in 2007, 2008, and 2013 when the effort in Statistical Area 030 was the higher. The diagnostics for each line model showed some departure from model assumptions, and the catch rate extremes were not well captured by the model (Figure E6).

### 3.2.2 Bottom trawl fishery

TCEPR tow-by-tow commercial data from vessels targeting hoki, hake or ling were analysed to produce a CPUE series, using the combined model. Overall a total of 122 unique vessels caught 130813 t from 91568 tows, and from these, 36 core vessels were selected (range 5-26 per year). and the core vessels caught an estimated 111561 t of ling from 73533 tows (Table F4, Figures F3). The spawning fishery included 32101 core tows with 218-2337 tows each year; the non-spawning fishery included 41432 tows with 508-4726 tows per year. The least active core vessel had participated in the fishery for only 5 years, but there were 28 vessels in the fishery for 8 or more years (with the maximum being 21 years). The proportion of zero catch tows (i.e., tows where either hoki, hake, or ling was targeted, but no ling was caught) for core vessels ranged between 0.05 and 0.36 per year, and showed an decreasing trend for both core and all vessels, although the trend flattened off from 2002 ( $0.05-0.12 \%$ ) (Table F4). Overall, 10372 (14.1\%) tows reported no ling catch.

Seven variables were selected into the lognormal model, resulting in a total $r^{2}$ of $55 \%$, with grid number explaining $35 \%$ of the residual deviance; for the binomial model, grid number explained $15.2 \%$ of the variance, with the final model explaining $22 \%$ (Table F5). The variables selected into the two-fishery lognormal and binomial models were similar to those for the single fishery model.The standardised year effects from the single, spawning and non-spawning fishery lognormal models showed a flat undulating trend (Table F5, Figure F4). Unstandardised indices for the lognormal models did not follow the same
trend as the standardised indices; they were generally lower in earlier and later years and higher in middle years, with the differences attributable mainly to the influence of the variables grid number and vessel (Figure F5). The binomial series showed a flat trend, so the combined indices are similar to the lognormal model (Figure F6). A lognormal model run using data from daytime hours in NovemberDecember on the Snares Shelf showed similar trends, as did lognormal analyses using top cell, top cells or complement of top cells, although much higher values were seen for earlier years for top cell. None of the trawl CPUE series matched the line CPUE series for any of the fisheries, or the trawl survey biomass series (Figure F7).

Influence plots (Figure F8) show that fleet dynamics and behaviour have changed: most variables had a negative effect in early years. Grid number had a large positive influence on CPUE from from 2004. Expected catch varied between grid number; it was highest around the Norwegian Hole and along the Snares Shelf (Statistical Areas 028, 030, 602, and 603) with the influence of Statistical areas on CPUE more positive in the north, and from September to December (see Figure C1 and F2). Vessel had a negative trend in influence until 1999, a positive trend from 1999 to 2011, and then little influence subsequently, suggesting a change in fleet dynamics. Vessels with more overall catch tended to have higher expected catches and lower variability. Influence of target species showed that there is a positive influence on CPUE when ling are targeted (as would be expected), and a negative influence when hoki are targeted, especially from 2006 to 2008. The probability of a zero ling catch varied markedly with grid number and vessel, and was higher for tows that were outside the 400-800 m depth range, and for tows targeting hoki or ling (Figure F9). Duration has a relatively weak effect on the probability of a zero ling catch, unless the tow was very short or long. The diagnostics for both lognormal and binomial models were considered acceptable, with substantial deviation from model assumptions only occurring outside two standard deviations (Figure F10).

### 3.2.3 CPUE summary

In recent assessments of ling stocks around the South Island, series of CPUE indices derived from commercial fisheries have been used as indices of abundance (e.g., Horn et al. 2013, Roberts 2016), usually as a sensitivity test in conjunction with indices from trawl survey series.

The Southland and Sub-Antarctic line CPUE series were variable with a declining trend for the single, spawning, and non-spawning fisheries. As would be expected, the trends in the indices, and the variables selected into the models, have not changed markedly between the previous (Ballara \& Horn 2015) and current analyses. The longline fisheries examined here target a single species using the same method, so the sets of variables selected into the model for each stock might be expected to have some similarities. In all the analyses, total hooks or log(total hooks) and statistical area were selected into the model. Vessel was accepted into the single fishery model. With the CPUE unit being 'kg per day', it would be expected that the number of hooks set per day would be a very influential variable, and it is indeed the most influential variable in the current analyses, accounting for the largest proportion of explained variance. Skill levels and/or gear efficiency will vary between vessels so the selection of a vessel variable in each model would be expected. Clearly, catch rates vary throughout the year, probably in relation to the spawning season for ling, although no time of year variables entered the model.

One clearly apparent change in recent line fishing seasons is the reduction in effort on the Campbell Plateau, and in particular for the spawning fishery since 2008. This reduction is attributable in part to the diversion of autoline vessels to the Ross Sea toothfish fishery, but also to the permanent removal from the New Zealand fleet of some large line vessels, and to a recent reduction in overseas demand for New Zealand ling (Ballara \& Horn 2015).

Horn (2002) concluded that most ling line CPUE series performed well in relation to four criteria raised by Dunn et al. (2000), and so were probably reasonable indices of abundance (for that part of the population targeted by the fishery). Although the longline fleet composition has changed over time, Horn (2004a) completed parallel analyses for shorter time series of data and compared the results with
the "all years" indices to show that the change in fleet dynamics did not bias the line CPUE. It is considered unlikely that line CPUE series have been seriously biased by any changes in fishing practice over the durations of the fisheries (Horn 2004b), although data on some potentially influential factors are either unavailable before 2004 (e.g., hook spacing) or would be difficult to incorporate into analyses (e.g., vessel skipper, learning by fishers). The current autolongline analysis further standardises the longline dataset by excluding handbait vessels with higher catch rates and more efficient hook types and baiting practices. Most longline vessels, however, were able to be identified as exclusively autolongline or handbait vessels, but due to lack of information there were a set of vessels that were current autolongliners but it was not clear whether they had previously converted from handbait to autolongline. Classification of these vessels into years when they fished as either handbait or as autolongline vessels would expand the dataset.

A combined TCEPR tow-by-tow model using QMS data from the Southland and Sub-Antarctic hoki, hake and ling target trawl fishery was updated. The $r^{2}$ values for the CPUE models were relatively high (55\%), and the retained variables exhibited many similarities between models, with most of the explanatory power from the first two or three variables. Locational variable grid number and target species were the most important variables in all analyses. There is a large volume of data used in the analysis, and all the tow-by-tow estimated catch CPUE series exhibit no trend. Unstandardised indices in all three datasets did not follow the same trend as the standardised indices; they were generally lower in earlier years and higher in later years, and the differences can be attributed mainly to the influence of the variables grid number and target species. The trends in the combined and lognormal indices were similar, implying that little was gained by adding data from zero catches into that analysis. There was no agreement between the Southland and Sub-Antarctic trawl survey biomass series and the CPUE series, although the biomass trend appeared closer to the single fishery model. CPUE series from both the trawl and line fisheries are available, and there are some differences in the trends from the two fishing methods. However, indices from a different data source in an individual stock would not necessarily be expected to exhibit similar trends, owing to different fishing selectivities in the different fisheries. There is no way of establishing whether this analysis is likely to produce a reliable index series.

The line CPUE was expected to provide a relatively unbiased CPUE index. However, biases in CPUE caused by changes in fishing practice not accounted for by the available predictors may still be present. This may be particularly pronounced for the ling target line fishery. For example, the line fishery generally targets ling on clearly defined geological features using relatively short longlines that can be accurately placed. The accurate placement of fishing gear in optimal ling habitat could bring about hyperstability in the CPUE index. Also, some interactions with the trawl fishery in the same area could also lead to biases, and it has been suggested that the hoki trawlers may direct the line vessels to areas with apparently high ling abundance, as indicated by the trawl bycatch (Horn \& Ballara 2012). This behaviour would enable line fishers to reduce their search time and/or fish in areas that are likely to produce relatively high, and consistently high, ling catch rates. If the extent of this behavior changed over time, it would bias the line CPUE. There are also anecdotal reports of trawlers directly transferring some of their ling catch (presumably for which they have no quota) to line or setnet boats; this behaviour would bias both trawl and line CPUE.

The current autolongline analysis rolls up data to vessel-day-statistical area, and for LCER and LTCER only uses data if ling is in the top five species (see Section 3.1). Since 2004, individual set data have been captured on LCER and LTCER forms (see Figure C5). There are now 14 years of individual set data, so it would be worthwhile to investigate a comparison of individual set information rather than a rolled up data set. This would also increase the number of records in a year, although would still not get around confidentiality issues where data cannot be reported if it is produced from fewer than 3 vessels in a year.

The diagnostic plots for both line and trawl lognormal models were unable to capture the extremes in catch rates and tended to underestimate the lower or higher catch rates. This suggests that the lognormal models can be improved, and there may be violations of model assumptions (i.e., the assumption of
normally distributed constant variance residual errors). Other models may need investigating. The diagnostics for the trawl binomial models were good and the quantile-quantile plots indicated very little deviation from the normal distribution of the residuals at both the lower and upper ends, i.e., very small and very large catch rates were well modelled.

## 4. ACKNOWLEDGMENTS

Thanks to Peter Horn, and members of the Deepwater Fisheries Assessment Working Group for useful discussions on this work, and to Peter Horn for a comprehensive review of this report. Also thanks to Richard Wells for providing information on longline vessel types. This work was funded by the Ministry for Primary Industries project LIN201701.

## 6. APPENDIX A: DESCRIPTIVE OVERALL

Table A1: Definitions of geographical areas used in the fisheries descriptive analyses (based on statistical areas), and the administrative ling stocks they approximate. For a plot of statistical areas, see Figure A2.

| Area | Statistical Areas | Administrative stock | Assessment stock |
| :--- | :--- | :--- | :--- |
| North NI | $041-048,001-010,101-110,801$ | LIN 1 | - |
| East NI | $011-015,201-206$ | LIN 2 | - |
| East SI | $018-024,301$ | LIN 3 | LIN 3\&4 |
| Chatham | $049-052,401-412$ | LIN 4 | LIN 3\&4 |
| Southland | $025-031,302,303,501-504$ | LIN 5 | LIN 5\&6 |
| Sub-Antarctic | $601-606,610-612,616-620,623-625$ | Part of LIN 6 | LIN 5\&6 |
| Bounty | $607-609,613-615,621,622$ | Part of LIN 6 | LIN 6B |
| West SI | $032-036,701-706$ | Part of LIN 7 | LIN 7WC |
| Cook Strait | $016,017,037-040$ | Parts of LIN 2 \& 7 | LIN 7CK |

Table A2: Estimated ling catch ( $t$ ) as reported on TCEPR, TCER, CELR, NCER, and LCER returns, reported landings ( $t$ ) from MHR records, and TACC ( $t$ ) by QMA and by assessment stock area (see Figure A1) from 1989-90 to 2016-17. All catches have been rounded to the nearest tonne. Fishing year 1989-90 is denoted as "1990", etc. The percentage of total estimated landings (Total) taken from each area is also presented (Percent). The QMR total also includes small catches from FMA 10 and outside the EEZ.

|  | Estimated catch |  |  |  |  |  |  |  |  |  |  |  |

Table A4: Catch of ling ( $t$ ) by area, by fishing year, for various fishing methods. Fishing year 1989-90 is denoted as "1990", etc. Values were rounded to the nearest tonne, so " 0 " represents estimated landings of less than 0.5 t , and "-" indicates nil reported landings. Total catches also includes catches from FMA 10 and outside the EEZ.
(a) Inshore bottom trawl (method BT and BPT on CELR and TCER forms)

Figure A1: Ling fishstocks, and the 1000 m isobath. The boundaries used to separate biological stock LIN 6B from the rest of LIN 6, and the west coast South Island section of LIN 7 from the rest of LIN 7, are shown as broken lines.

Figure A2: Definitions of geographical areas used in the analyses (based on statistical areas). See Table A1 for the administrative ling stocks they approximate.

Figure A3: Distribution of annual catch by area, form type, fishing method, target species, month, and vessel length for all ling catches by all methods. Circle size is proportional to catch; maximum circle size is indicated in the heading of each plot. Form types: CEL is Catch, Effort, Landing Return; LCE is Lining Catch Effort return; LTC is Lining Trip Catch, Effort return; NCE is Netting Catch Effort Return; TCE is Trawl Catch Effort Return; TCP is Trawl Catch Effort, and Processing Return. Method definitions: BLL, bottom longlining; BT, bottom trawl; CP, cod potting; DL, dahn lines; MB, midwater trawl on the bottom; MW, midwater trawl; SN, set net; TL, trot line. Species codes: BAR, barracouta; BNS, bluenose; HAK, hake; HOK, hoki; LIN, ling; RCO, red cod; SCI, scampi; SQU, arrow squid; SWA, silver warehou; WWA, white warehou.

Figure A4: Distribution of annual catch by area, form type, fishing method (by form type), target species, month, and vessel length for all ling catches by trawl methods. Circle size is proportional to catch; maximum circle size is indicated in the heading of each plot. Form types and method types are defined in Figure A3. Species codes: BAR, barracouta; GIZ, giant stargazer; HAK, hake; HOK, hoki; LIN, ling; RCO, red cod; SCI, scampi; SQU, arrow squid; SWA, silver warehou; WWA, white warehou.

Figure A5: Distribution of annual catch by area, form type, fishing method (by form type), target species, month, and vessel length for all ling catches by line methods. Circle size is proportional to catch; maximum circle size is indicated in the heading of each plot. Form types and method types are defined in Figure A3. BAS, bass; BNS, bluenose; BSH, seal shark; HAP, hapuku; HPB, hapuku and bass; LIN, ling; RIB, ribaldo; SCH, school shark; SKI, gemfish; SPO, rig.

## 7. APPENDIX B: DESCRIPTIVE EAST SI AND CHATHAM (LIN 3\&4)

Table B1: East SI and Chatham (LIN 3\&4) trawl and line catch by target species and fishing method, 198990 to 2016-17. Values have been rounded to the nearest tonne, so ' 0 ' denotes catches from 1 to 499 kg and '-' denotes zero catch.

| Fishing | Trawl fishery |  |  |  | Line fishery |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Hake | Hoki | Ling | Other | Ling | Other |
| 1989-90 | 22 | 574 | 313 | 264 | 190 | 3 |

Figure B1: East SI and Chatham (LIN 3\&4) trawl; distribution of annual catch by statistical area, form type, fishing method (by form type), target species, month, and vessel length. Circle size is proportional to catch; maximum circle size is indicated in the heading of each plot. Species codes: BAR, barracouta; HAK, hake; HOK, hoki; LIN, ling; RCO, red cod; SCI, scampi; SPD, spiny dogfish; SPE, sea perch; SQU, arrow squid; SWA, silver warehou.

Trawl: 1990-1996

Figure B2: Density plots of East SI and Chatham (LIN 3\&4) commercial ling trawl catches, for combined fishing year groups (labelled by year-ending).

Trawl: 2017

Figure B3: Density plots of East SI and Chatham (LIN 3\&4) commercial ling trawl catches for the 20142017 fishing years (labelled by year-ending).

Figure B4: East SI and Chatham (LIN 3\&4) bottom trawl; means of effort variables by fishing year for tows targeting ling, or targeting hake, hoki, or ling.

Figure B5: East SI and Chatham (LIN 3\&4) line fishery distribution of annual catch by statistical area, form type, fishing method (by form type), target species, month, and vessel length. Circle size is proportional to catch; maximum circle size is indicated in the heading of each plot. Species codes: BNS, bluenose; HAP, hapuku; HPB, hapuku and bass; LIN, ling; RIB, ribaldo; SCH, school shark.

Figure B6: Density plots of East SI and Chatham (LIN 3\&4) commercial ling line fishery catches for combined fishing year groups (labelled by year-ending).

Figure B7: Density plots of East SI and Chatham (LIN 3\&4) commercial ling line fishery catches for each of the 2014-2017 fishing years (labelled by year-ending).

Figure B8: East SI and Chatham (LIN 3\&4) bottom longline fishery; means of effort variables by fishing year for sets targeting ling (Target LIN) or targeting ling and other target species (All).

## 8. APPENDIX C: DESCRIPTIVE SOUTHLAND AND SUB-ANTARCTIC (LIN 5\&6)

Table C1: Southland and Sub-Antarctic (LIN 5\&6) trawl and line catch by target species and fishing method, 1989-90 to 2016-17 by area. Values have been rounded to the nearest tonne, so ' 0 ' denotes catches from 1 to 499 kg and '-' denotes zero catch.

Figure C1: Southland and Sub-Antarctic (LIN 5\&6) trawl fishery; distribution of annual catch by statistical area, form type, fishing method (by form type), target species, month, and vessel length. Circle size is proportional to catch; maximum circle size is indicated in the heading of each plot. Species codes: GIZ, giant stargazer; HAK, hake; HOK, hoki; LIN, ling; RCO, red cod; SBW, southern blue whiting; SCI, scampi; SQU, arrow squid; SWA, silver warehou; WWA, white warehou.

Figure C2: Density plots of Southland and Sub-Antarctic (LIN 5\&6) commercial ling trawl catches for combined fishing year groups (labelled by year-ending).

Trawl: 2015

Trawl: 2014

Trawl: 2016

Figure C3: Density plots of Southland and Sub-Antarctic (LIN 5\&6) commercial ling trawl catches for each of the 2014-2017 fishing years (labelled by year-ending).

Figure C4: Southland and Sub-Antarctic (LIN 5\&6) bottom trawl fishery; means of effort variables by fishing year for tows targeting ling, or targeting hake, hoki, or ling.

Figure C5a: Southland and Sub-Antarctic (LIN 5\&6) line fishery distribution of annual catch by statistical area, form type, fishing method (by form type), target species, month, and vessel length. Circle size is proportional to catch; maximum circle size is indicated in the heading of each plot. Species codes: BNS, bluenose; HAP: hapuku; HPB, hapuku and bass; LIN, ling; PTO, Patagonian toothfish; SCH, school shark.

Figure C5b: Southland and Sub-Antarctic (LIN 5\&6) continued. Distribution of Southland and SubAntarctic ling line fishery catch by month for Puysegur (Statistical Area 030) and non-Puysegur for the 1990 to 2017 calendar years. Circle size is proportional to catch; maximum circle size is indicated on the top left hand corner of each plot.

Figure C6: Density plots of Southland and Sub-Antarctic (LIN 5\&6) commercial ling line catches for combined fishing year groups (labelled by year-ending).

Figure C7: Density plots of Southland and Sub-Antarctic (LIN 5\&6) commercial ling line catches for each of the 2014-2017 fishing years (labelled by year-ending).

Figure C8: Southland and Sub-Antarctic (LIN 5\&6) bottom longline fishery; means of effort variables by fishing year for sets targeting ling (Target LIN), or or targeting ling and other target species ling (All).

## 9. APPENDIX D: DESCRIPTIVE WEST SI (LIN 7WC)

Table D1: West SI (LIN 7 WC) trawl and line catch by target species and fishing method, 1989-90 to 201617. Values have been rounded to the nearest tonne, so ' 0 ' denotes catches from 1 to 499 kg and '-' denotes zero catch.

| Year | Trawl fishery |  |  |  | Line fishery |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Figure D1: West SI (LIN 7 WC) trawl fishery; distribution of annual catch by statistical area, form type, fishing method (by form type), target species, month, and vessel length. Circle size is proportional to catch; maximum circle size is indicated in the heading of each plot. Species codes: BAR, barracouta; GIZ, giant stargazer; HAK, hake; HOK, hoki; LDO, lookdown dory; LIN, ling; NMP, tarakihi; RCO, red cod; RSO, gemfish; SWA, silver warehou.

Figure D2: Density plots of West SI (LIN 7 WC) commercial ling trawl catches for combined fishing year groups (labelled by year-ending).

Figure D3: Density plots of West SI (LIN 7 WC) commercial ling trawl catches for each of the 2014-2017 fishing years (labelled by year-ending).

Figure D4: West SI (LIN 7WC) trawl fishery; means of effort variables by fishing year for tows targeting hake, hoki, or ling, for all tows (All), bottom tows (BT), and midwater tows (MW).

Figure D5: West SI (LIN 7 WC) line fishery distribution of annual catch by statistical area, form type, fishing method (by form type), target species, month, and vessel length. Circle size is proportional to catch; maximum circle size is indicated in the heading of each plot. Species codes: BNS, bluenose; BSH, seal shark; HAP, hapuku; HPB, hapuku and bass; LIN, ling; SCH, school shark.

Figure D6: Density plots of West SI (LIN 7 WC) commercial ling line fishery catches for combined fishing year groups (labelled by year-ending).

Figure D7: Density plots of West SI (LIN 7 WC) commercial ling line fishery catches for each of the 20142017 fishing years (labelled by year-ending).

Figure D8: West SI (LIN 7WC) bottom longline fishery; means of effort variables by fishing year for sets targeting ling (Target LIN), or or targeting ling and other target species (All).

## 10. APPENDIX E: SOUTHLAND AND SUB-ANTARCTIC LINE CPUE (LIN 5\&6)

Table E1: Summary of predictors offered in the Southland and Sub-Antarctic CPUE models for the line fisheries.

| Variable | Type | Description |
| :--- | :--- | :--- |
| Year | Categorical | Calendar year |
| Month | Categorical | Month of year |
| Statistical area | Categorical | Statistical area for the set or tow |
| Vessel | Categorical | Unique vessel identifier |
| Day of year | Continuous | Julian day, starting at 1 on 1 January |
| Method | Categorical | Fishing method (bottom longline, trot line, dahn line) |
| Total hooks | Continuous | Number of hooks set per day in a statistical area |
| Log(Total hooks) | Continuous | Logarithm of variable Total hooks |
| Number of sets | Continuous | Number of set per day in a statistical area |
| Log(Number of sets) | Continuous | Logarithm of variable Number of sets |
| CPUE | Continuous | Ling catch (kg) per day in a statistical area |

Table E2: Percentage of catches, vessel-days, and vessels by vessel type and year groups in the Southland and Sub-Antarctic fishery (LIN 5\&6) line fishery. Vessel type: Always auto, vessel has always been an autolongliner; Auto now, currently an autolongline vessel but no information as to whether it converted from Handbait to autolongline in the past; and Handbait, Handbait longliner. Year defined as SeptemberAugust.

| Year | Catches (t) |  |  | Number of vessel-days |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Always auto | Auto now | Handbait | Always auto | Auto now | Handbait |
| 1992-1995 | 92.8 | 6.0 | 1.1 | 84.6 | 7.7 | 7.6 |
| 1996-1999 | 88.4 | 11.2 | 0.5 | 83.2 | 13.9 | 3.0 |
| 2000-2003 | 87.7 | 12.3 | - | 81.1 | 18.6 | 0.3 |
| 2004-2007 | 99.9 | 0.1 | - | 98.7 | 1.3 | - |
| 2008-2011 | 82.5 | 11.9 | 5.6 | 61.8 | 23.1 | 15.1 |
| 2012-2015 | 90.9 | 0.0 | 9.1 | 81.5 | - | 18.5 |
| 2016-2017 | 78.6 | 3.6 | 17.8 | 74.2 | 5.7 | 20.0 |
| Total | 89.5 | 8.0 | 2.5 | 81.8 | 11.4 | 6.9 |
| Year | Number of vessels |  |  |  |  |  |
|  | Always auto | Auto now | Handbait |  |  |  |
| 1992-1995 | 25.0 | 25.0 | 50.0 |  |  |  |
| 1996-1999 | 35.3 | 23.5 | 41.2 |  |  |  |
| 2000-2003 | 50.0 | 37.5 | 12.5 |  |  |  |
| 2004-2007 | 80.0 | 20.0 | - |  |  |  |
| 2008-2011 | 36.4 | 18.2 | 45.5 |  |  |  |
| 2012-2015 | 25.0 | - | 75.0 |  |  |  |
| 2016-2017 | 33.3 | 11.1 | 55.6 |  |  |  |
| Total | 24.4 | 19.5 | 56.1 |  |  |  |

Table E3: CPUE data constraints by area for Southland and Sub-Antarctic line vessels.

|  | Bottom longline data |
| :--- | :--- |
| Data source | CELR (all catch), LTCER and LCER (ling catch included only if ling is one of the top |
|  | 5 species by weight caught in a day's fishing for a vessel/stat area) |
| Year range | 1991-2017 |
| Year definition | September-August |
| Statistical areas | At least 50 sets: 026, 029, 030, 031, 602-605, 610, 611, 612, 618, 619, 625 |
| Method | BLL |
| Target | LIN |
| Vessel type | Always autolongline |
| Catch | $1-35000$ kg |
| Total number of hooks | $50-50000$ |
| Core vessel selection | Approx. $89 \%$ of catch, $\geq 2$ years vessel participation |

Table E4: Variables retained in the Southland and Sub-Antarctic (LIN 5\&6) line GLMs order of decreasing explanatory value, for each model lognormal and fishery, with the corresponding deviance explained (Rsquared, \%).
(a) Single line fishery - vessels that have always been autolongline

| Variable | R-squared |
| :--- | ---: |
| Year | 8.99 |
| Number of hooks | 54.27 |
| Statistical area | 60.33 |
| Vessel | 61.50 |

(b)Two fishery model - vessels that have always been autolongline

| Variable | R-squared |
| :--- | ---: |
| Year | 20.21 |
| Number of hooks | 60.20 |
| Statistical area | 62.12 |

Table E5: CPUE standardised year lognormal indices for Southland and Sub-Antarctic line fisheries for vessels that have always been autolongline vessels (with CVs). Year defined as September-August for the single model, September-December for the spawning model, and January-August for the non-spawning model.

|  | Single line fishery |  |  | Spawning fishery |  |  | Non-spawning fishery |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Year | Index | CI | CV | Index | CI | CV | Index | CI | CV |
| 1992 | 1.00 | 0.82-1.21 | 0.10 | 1.03 | 0.80-1.33 | 0.13 | 1.15 | 0.94-1.40 | 0.10 |
| 1993 | 1.39 | 1.16-1.66 | 0.09 | 1.76 | 1.47-2.10 | 0.09 | 1.16 | 0.93-1.44 | 0.11 |

Figure E1: Southland and Sub-Antarctic autolongline single fishery fishing effort and catches by year for individual vessels (denoted anonymously by number on the $y$-axis) in core CPUE analyses. Circle area is proportional to the effort or catch. Year defined as September-August.

Southland and Sub-Antarctic: non-spawning fishery model

Figure E2: Year index from the lognormal model for each Southland and Sub-Antarctic autolongline fishery. Bars indicate $95 \%$ confidence intervals. Year defined as September-August for the single model, September-December for the spawning model, and January-August for the non-spawning model.

Figure E3: Addition of variables into the lognormal CPUE model for each Southland and Sub-Antarctic autolongline fishery. Year defined as September-August for the single model, September-December for the spawning model, and January-August for the non-spawning model.

Southland and Sub-Antarctic: spawning autolongline fishery

Southland and Sub-Antarctic: non-spawning autolongline fishery

Figure E4a: CPUE indices for the lognormal model for the Southland and Sub-Antarctic autolongline single and two fishery (spawning and non-spawning fisheries). Year defined as September-August for the single model, September-December for the spawning model, and January-August for the non-spawning model.

Figure E4b: CPUE indices for the lognormal model for the Southland and Sub-Antarctic single fishery (spawning and nonspawning) and two fishery (spawning and non-spawning) models, comparing the current core vessel analysis with the previous analysis. For the current analysis year is defined as SeptemberAugust for the single model, September-December for the spawning model, and January-August for the non-spawning model.

Figure E4c: Comparison of the Southland and Sub-Antarctic CPUE autolongline models to Southland and Sub-Antarctic Tangaroa ling trawl survey biomass indices. Year defined as September-August for the single model, September-December for the spawning model, and January-August for the non-spawning model.

Figure E5: Effect and influence of non-interaction term variables in the Southland and Sub-Antarctic single autolongline lognormal model. Top: relative effect by level of each variable. Bottom left: relative distribution of each variable by fishing year. Bottom right: influence of variable on unstandardised CPUE by year. Year defined as September-August.

Southland and Sub-Antarctic: single fishery model

Southland and Sub-Antarctic: two fishery model

Figure E6: Diagnostic plots for the Southland and Sub-Antarctic single and two fishery lognormal autolongline CPUE models.

## 11. APPENDIX F: SOUTHLAND AND SUB-ANTARCTIC TRAWL CPUE (LIN 5\&6)

Table F1: Summary of predictors offered in the Southland and Sub-Antarctic CPUE models for the trawl fisheries.

| Variable | Type | Description |
| :--- | :--- | :--- |
| Year | Categorical | Fishing year, or June-September |
| Month | Categorical | Month of year |
| Statistical area | Categorical | Statistical area for the set or tow |
| Vessel | Categorical | Unique vessel identifier |
| Day of year | Continuous | Julian day, starting at 1 on 1 January |
| Method | Categorical | Trawl method (bottom trawl, midwater trawl on bottom, midwater trawl) |
| Twin trawl | Categorical | Vessel did or did not use a twin trawl |
| Number of nets | Categorial | Number of nets used in a trawl |
| Headline height | Continuous | Distance between trawl headline and groundrope (m) |
| Duration | Continuous | Tow duration, in hours |
| Start time | Continuous | Start time of tow, 24-hour clock |
| Mid time | Continuous | Time at the midpoint of the tow, 24-hour clock |
| Depth bottom | Continuous | Bottom depth (m) |
| Depth net | Continuous | Depth of groundrope (m) |
| Speed | Continuous | Towing speed (kts) |
| Latitude | Continuous | Start latitude of tow |
| Longitude | Continuous | Start longitude of tow |
| CPUE | Continuous | Ling catch (kg) per tow |
| Grid number | Categorical | 0.5 degree square based on start latitude and longitude of tow |

Table F2: Number of female ling gonads staged by observers from commercial trawl catches by month sampled from each area by the observer programme for fishing years 1990-91 to 2016-17 where data exist. Areas defined in Figure A1. Stages are: 1, resting or immature; 2, ripening; 3, ripe; 4, running ripe and partially spent; 5 , spent.
(a) Southland and Sub-Antarctic (excluding Puysegur)

| Stage | Month |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

< 50 t
150-1000 m

## $0.2-15$ hours

Approx. $80 \%$ of catch, $\geq 5$ years vessel participation, at least 20 tows per vessel-year

Table F4: Summary of data for all vessels and for vessels included in the core Southland and Sub-Antarctic (LIN 5\&6) CPUE standardisation datasets. Data include: number of unique vessels fishing (Vessels), number of tow records for non-zero and zero ling catches for trawl data (Effort), proportion of tows that caught zero catch (Zeros), estimated catch, and unstandardised CPUE from non-zero catches from the tow-by-tow data. Year defined as September-August for the single model, September-December for the spawning model, and January-August for the non-spawning model.
(a) Single trawl fishery

|  | All vessels |  |  |  |  | Core vessels |  |  |  |  |

Table F5: Variables retained in the GLMs order of decreasing explanatory value, for each Southland and Sub-Antarctic (LIN 5\&6) trawl model (lognormal, binomial), with the corresponding deviance explained (R-squared, \%).
(a) Single trawl fishery

|  | Lognormal |  | Binomial |  |
| :--- | ---: | :--- | :--- | ---: |
| Variable | R-squared |  |  |  |
| Year | 10.73 |  | Variable | R-squared |
| Grid number | 34.77 |  | Grid number | 3.32 |
| Target species | 44.71 |  | Vessel | 15.22 |
| Mid time of tow | 48.34 |  | Depth of bottom | 18.03 |
| Vessel | 51.12 |  | Target species | 19.79 |
| Month | 53.44 |  | 21.39 |  |
| Duration | 55.31 |  | Duration | 22.43 |

(b) Two trawl fishery model

|  | Lognormal |  | Binomial |  |
| :--- | ---: | :--- | :--- | ---: |
| Variable | R-squared |  |  |  |
| Year | 19.69 |  | Variable | R-squared |
| Grid number | 38.32 |  | Grid number | 4.23 |
| Target species | 46.00 |  | Vessel | 15.87 |
| Vessel | 49.74 |  | Depth of bottom | 18.65 |
| Mid time of tow | 52.01 |  | Target species | 20.43 |
| Month | 53.95 |  | 22.04 |  |
| Duration | 55.80 |  | Duration | 23.09 |

Table F6: CPUE standardised indices for Southland and Sub-Antarctic trawl fisheries (LIN 5\&6), and binomial, and combined CPUE indices for trawl indices (with CVs). Year defined as September-August for the single model, September-December for the spawning model, and January-August for the nonspawning model.

Figure F1: Gonad stages of female ling sampled by observers from commercial trawl catches, by month and area. Areas defined in Figure A1. Sub-Antarctic gonad stages include "Southland and "Sub-Antarctic" areas (see Figure A2) but excludes "Puysegur". Stages are: 1, resting or immature (yellow); 2, ripening (orange); 3 , ripe (light blue); 4 , running ripe and partially spent (red); 5 , spent (blue).

Figure F2: Density plots (latitude and longitude, and $0.5^{\circ}$ grid cells) of commercial ling catches from TCEPR tow-by-tow datasets for target hake, hoki, and ling tows, for all years combined, with the grid cells producing the top five catch totals marked (1: gold cross; 2: orange diamond; 3: red triangle; 4: red cross; 5: purple triangle).

Figure F3: Southland and Sub-Antarctic single trawl fishing effort and catches by year for individual vessels (denoted anonymously by number on the $y$-axis) in core CPUE analyses in the single trawl fishery. Circle area is proportional to the effort or catch. Year defined as September-August.

Figure F4: Year index from the lognormal model for each Southland and Sub-Antarctic trawl fishery. Bars indicate 95\% confidence intervals. Year defined as September-August for the single model, SeptemberDecember for the spawning model, and January-August for the non-spawning model.

Southland and Sub-Antarctic: single trawl fishery

Southland and Sub-Antarctic: spawning trawl fishery

Figure F5: Effects of the addition of variables into the lognormal CPUE model for each Southland and SubAntarctic trawl fishery. Year defined as September-August for the single model, September-December for the spawning model, and January-August for the non-spawning model.

Figure F6: Southland and Sub-Antarctic indices from the lognormal, binomial and combined model for each fishery. Bars indicate $\mathbf{9 5 \%}$ confidence intervals. Year defined as September-August for the single model, September-December for the spawning model, and January-August for the non-spawning model. The horizontal dotted line shows the mean of the combined series. The probability scale relates to the binomial and raw proportion non-zero series.

Figure F7a: Comparison of CPUE indices for the lognormal model for the Southland and Sub-Antarctic single September-August fishery with the Snares Shelf November-December daytime single fishery model (top), and the Snares Shelf November-December daytime single fishery model with the Southland and SubAntarctic Tangaroa ling trawl survey biomass indices.

Figure F7b: CPUE indices for the combined model for the Southland and Sub-Antarctic single fishery (both spawning and non-spawning) comparing the current core vessel analysis with other cell models. The bottom plot is on a smaller $y$-axis scale, so trends can be seen, and excludes the top cell indices, but includes the Southland and Sub-Antarctic Tangaroa November-December ling trawl survey biomass indices. Year defined as September-August.

Figure F7c: CPUE indices for the combined model for the Southland and Sub-Antarctic single (two fisheries) and two fishery (spawning and non-spawning) models, comparing the current core vessel analysis with the longline CPUE indices. Year defined as September-August for the single model, SeptemberDecember for the spawning model, and January-August for the non-spawning model.

Southland and Sub-Antarctic: trawl fishery combined models

Figure F7d: CPUE indices for the combined model for the Southland and Sub-Antarctic single fisheries and two fishery (spawning and non-spawning) models, comparing the current core vessel analysis with the Southland and Sub-Antarctic Tangaroa ling trawl survey abundance indices. Year defined as SeptemberAugust for the single model, September-December for the spawning model, and January-August for the non-spawning model.

Figure F8: Effect and influence of non-interaction term variables in the Southland and Sub-Antarctic trawl core vessel lognormal model. Top: relative effect by level of each variable. Bottom left: relative distribution of each variable by year. Year defined as September-August. Bottom right: influence of variable on unstandardised CPUE by fishing year.

Figure F9: Expected variable effects for variables selected into the CPUE binomial model for the SubAntarctic TCEPR tow-by-tow core vessel single fishery, 1991-2017. The $95 \%$ confidence intervals are shown as bars for categorical variables and as upper and lower lines for continuous variables. Year defined as September-August.

Southland and Sub-Antarctic: single trawl fishery model

Southland and Sub-Antarctic: two trawl fishery model

Figure F10a: Diagnostic plots for the Southland and Sub-Antarctic single and two fishery lognormal trawl CPUE models.

Southland and Sub-Antarctic: single trawl fishery model

Southland and Sub-Antarctic: two trawl fishery model

Figure F10b: Diagnostic (residual and q-q) plots for the Southland and Sub-Antarctic single and two fishery binomial trawl CPUE models.
